Course: Biology 101

Date: October 2026

Question: Describe the mechanism of photosynthesis in green plants.

Answer:

Photosynthesis is the chemical process by which green plants convert light energy into chemical energy.

Plants absorb sunlight through chlorophyll pigments located in their chloroplasts.

Using water absorbed by the roots and carbon dioxide taken in through stomata, plants produce glucose.

The overall formula is $6\text{CO}_2 + 6\text{H}_2\text{O} + \text{light} \rightarrow \text{C}_6\text{H}_{12}\text{O}_6 + 6\text{O}_2$.

The glucose is used for cellular energy while oxygen is released into the atmosphere.
